

Homework #8

Assigned: Wednesday March 30, 2022

Due: Tuesday April 5, 2022 @ 11:59pm ET/Boston

–5%: Wednesday April 6, 2022 @ 11:59pm ET/Boston

–10%: Thursday April 7, 2022 @ 11:59pm ET/Boston

Instructions:

- Homework is due on Tuesday at 11:59pm ET/Boston. Homeworks received up to 24 hours late (11:59pm ET on Wednesday) will be penalized 5 percent. Homeworks received up to 48 hours late (11:59pm ET on Thursday) will be penalized 10 percent. *NO* assignment will be accepted after 48 hours.
- We expect that you will study with friends and fellow students and you are welcome to verbally discuss the problems openly. However, your solution writeup should be the product of your own mind and expressed in your own words. The TAs and I will be available to answer specific questions or address specific points of confusion but we will not verify your answers prior to submission.
- Assignments should be typed using Word or LaTeX, or hand-written *neatly*. When submitting to gradescope be sure to indicate the page containing your answer to each problem, so that the TAs don't have to search for your solution.
- *To get full credit, explain your solution and show each step of the solution process!* Simply writing down a correct answer will receive little or no credit. We don't need your scratch work or draft solutions, only your final solution explaining your step-by-step reasoning. Recommendation: try to imagine you need to explain your solution to someone not in this class.
- If you think the TA made a clerical error in grading your assignment, you may submit a regrade request on Gradescope within 1 week of the publication of the grades. After 1 week of publication, ALL GRADES ARE FINAL.

Problem 1 [25 points (8,8,9)]: Conditional Probability

We are given 5 cards. 3 of the cards are black and they are numbered 1, 2, 3. The other two cards are red and they are numbered 1, 2.

We pick 2 random cards.

- i. What is the probability that both cards are red?
- ii. What is the probability that both cards are red, if we know that at least one of them is red?
- iii. What is the probability that both cards are red, if we know that one of them is red card number 1?

Problem 2 [25 pts (10,15)]: At the carnival!

At a carnival, you are trying to throw balls into 4 colored pots. The pots are colored red, blue, green, and pink. You will throw each ball one at a time into these pots. However, you must play this game blindfolded. The game pays out as follows

- \$1 for each ball in the red pot
- \$2 for each ball in the blue pot
- \$3 for each ball in the green pot
- \$4 for each ball in the pink pot

How many points do you expect to score:

- i. Assuming every ball lands in some hole with equal probability?
- ii. Assuming every ball has a 1 in 3 chance of not landing in any pot (and thus giving you no payout) but is otherwise equally likely to land in any pot?

Problem 3 [25 pts (5 pts each)]: Probability

Let $W(x)$ be the number of 1's in the binary representation of x . For example, $W(5) = W(00101_2) = 2$ because there are 2 1's in the binary representation of 5. This is sometimes called the *weight* of the binary number. A deck of 32 cards has numbers 0 to 31_{10} written in 5-bit binary ($00000_2 \dots 11111_2$).

1. What is the probability that the weight of a randomly chosen card is exactly 3?
2. What is the probability that the weight of the card is 3 and the number on the card is odd, *i.e.*, $P(W = 3 \cap \text{Odd})$?
3. Calculate $P(\text{Odd} | W = 3)$, the probability that the card represents an odd number given that the weight of the number is 3.
4. You are now dealt 3 random cards. What is the expected value for the total weight of your three-card hand?
5. What is the probability that the total weight of the three cards you were dealt is equal to 13? You may leave your answer as a simple expression.

Problem 4 [25 pts (5,10,10)]: Medical Testing and Bayes

A certain virus is spreading rapidly through the population and doctors have come up with a new but imperfect test to determine if a patient is infected.

- 20 percent of the population is already infected with the virus.
- 90 percent of infected patients test positive.
- 50 percent of healthy uninfected patients also test positive.

For this section, express your answer as a **simple fraction or number**.

1. What is the probability that a random person tests positive?
2. What is the probability that a random person who tests positive actually has the virus?
3. Suppose an independent second test is performed on a patient that previously tested positive. This time, the test result is negative. Now what is the probability that the patient is infected with the virus?
